#### Neural ODE

## Adjoint functions

$$\mathbf{a_z}(t) = \frac{\partial L(\mathbf{y})}{\partial \mathbf{z}(t)}; \quad \mathbf{a_{\theta}}(t) = \frac{\partial L(\mathbf{y})}{\partial \theta(t)}.$$

# Theorem (Pontryagin)

$$\frac{d\mathbf{a}_{\mathbf{z}}(t)}{dt} = -\mathbf{a}_{\mathbf{z}}(t)^{\mathsf{T}} \cdot \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}}; \quad \frac{d\mathbf{a}_{\boldsymbol{\theta}}(t)}{dt} = -\mathbf{a}_{\mathbf{z}}(t)^{\mathsf{T}} \cdot \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \boldsymbol{\theta}}.$$

Do we know any initilal condition?

#### Solution for adjoint function

$$\frac{\partial L}{\partial \boldsymbol{\theta}(t_0)} = \mathbf{a}_{\boldsymbol{\theta}}(t_0) = -\int_{t_1}^{t_0} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \boldsymbol{\theta}(t)} dt + 0$$
$$\frac{\partial L}{\partial \mathbf{z}(t_0)} = \mathbf{a}_{\mathbf{z}}(t_0) = -\int_{t_1}^{t_0} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}(t)} dt + \frac{\partial L}{\partial \mathbf{z}(t_1)}$$

Note: These equations are solved back in time.

#### Neural ODE

# Forward pass

$$\mathbf{z}(t_1) = \int_{t_0}^{t_1} f(\mathbf{z}(t), oldsymbol{ heta}) dt + \mathbf{z}_0 \quad \Rightarrow \quad \mathsf{ODE} \; \mathsf{Solver}$$

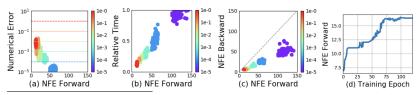

## Backward pass

Backward pass
$$\frac{\partial L}{\partial \boldsymbol{\theta}(t_0)} = \mathbf{a}_{\boldsymbol{\theta}}(t_0) = -\int_{t_1}^{t_0} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \boldsymbol{\theta}(t)} dt + 0$$

$$\frac{\partial L}{\partial \mathbf{z}(t_0)} = \mathbf{a}_{\mathbf{z}}(t_0) = -\int_{t_1}^{t_0} \mathbf{a}_{\mathbf{z}}(t)^T \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}(t)} dt + \frac{\partial L}{\partial \mathbf{z}(t_1)}$$

$$\mathbf{z}(t_0) = -\int_{t_1}^{t_0} f(\mathbf{z}(t), \boldsymbol{\theta}) dt + \mathbf{z}_1.$$

**Note:** These scary formulas are the standard backprop in the discrete case.

# Continuous Normalizing Flows

Discrete Normalizing Flows

$$\mathbf{z}_{t+1} = f(\mathbf{z}_t, \boldsymbol{\theta}); \quad \log p(\mathbf{z}_{t+1}) = \log p(\mathbf{z}_t) - \log \left| \det \frac{\partial f(\mathbf{z}_t, \boldsymbol{\theta})}{\partial \mathbf{z}_t} \right|.$$

Continuous-in-time dynamic transformation

$$\frac{d\mathbf{z}(t)}{dt} = f(\mathbf{z}(t), \boldsymbol{\theta}).$$

Assume that function f is uniformly Lipschitz continuous in  $\mathbf{z}$  and continuous in t. From Picard's existence theorem, it follows that the above ODE has a **unique solution**.

Forward and inverse transforms

$$\mathbf{z} = \mathbf{z}(t_1) = \mathbf{z}(t_0) + \int_{t_0}^{t_1} f(\mathbf{z}(t), \boldsymbol{\theta}) dt$$
 $\mathbf{z} = \mathbf{z}(t_0) = \mathbf{z}(t_1) + \int_{t_0}^{t_0} f(\mathbf{z}(t), \boldsymbol{\theta}) dt$ 

Papamakarios G. et al. Normalizing flows for probabilistic modeling and inference, 2019

# Continuous Normalizing Flows

To train this flow we have to get the way to calculate the density  $p(\mathbf{z}(t))$ .

# Theorem (special case of Kolmogorov-Fokker-Planck)

if function f is uniformly Lipschitz continuous in  ${\bf z}$  and continuous in  ${\bf t}$ , then

$$\frac{d \log p(\mathbf{z}(t))}{dt} = -\operatorname{trace}\left(\frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}(t)}\right).$$

**Note:** Unlike discrete-in-time flows, the function f does not need to be bijective, because uniqueness guarantees that the entire transformation is automatically bijective.

#### Density evaluation

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \log p(\mathbf{z}) - \int_{t_0}^{t_1} \operatorname{trace}\left(\frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}(t)}\right) dt.$$

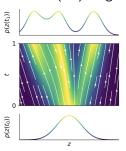

Adjoint method is used to integral evaluation.

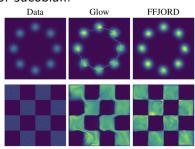

# Continuous Normalizing Flows

Forward transform + log-density

$$\begin{bmatrix} \mathbf{x} \\ \log p(\mathbf{x}|\boldsymbol{\theta}) \end{bmatrix} = \begin{bmatrix} \mathbf{z} \\ \log p(\mathbf{z}) \end{bmatrix} + \int_{t_0}^{t_1} \begin{bmatrix} f(\mathbf{z}(t), \boldsymbol{\theta}) \\ -\text{trace} \left( \frac{\partial f(\mathbf{z}(t), \boldsymbol{\theta})}{\partial \mathbf{z}(t)} \right) \end{bmatrix} dt.$$

- ▶ Discrete-in-time normalizing flows need invertible f. It costs  $O(d^3)$  to get determinant of Jacobian.
- ► Continuous-in-time flows require only smoothness of f. It costs  $O(d^2)$  to get trace of Jacobian.

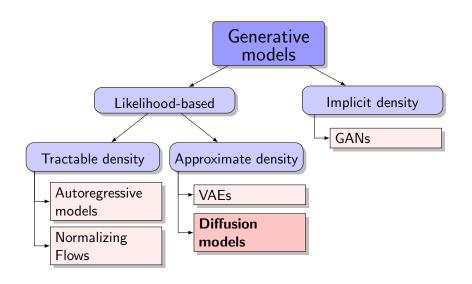

Grathwohl W. et al. FFJORD: Free-form Continuous Dynamics for Scalable Reversible Generative Models. 2018

#### Generative models zoo

# Langevin dynamic

Imagine that we have some generative model  $p(\mathbf{x}|\theta)$ .

#### Statement

Let  $\mathbf{x}_0$  be a random vector. Then under mild regularity conditions for small enough  $\eta$  samples from the following dynamics

$$\mathbf{x}_{t+1} = \mathbf{x}_t + \eta \frac{1}{2} \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t | \boldsymbol{\theta}) + \sqrt{\eta} \cdot \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(0, 1).$$

will comes from  $p(\mathbf{x}|\theta)$ .

What do we get if  $\epsilon = \mathbf{0}$ ?

Energy-based model

$$\begin{split} p(\mathbf{x}|\boldsymbol{\theta}) &= \frac{\hat{p}(\mathbf{x}|\boldsymbol{\theta})}{Z_{\boldsymbol{\theta}}}, \quad \text{where } Z_{\boldsymbol{\theta}} = \int \hat{p}(\mathbf{x}|\boldsymbol{\theta}) d\mathbf{x} \\ \nabla_{\mathbf{x}} \log p(\mathbf{x}|\boldsymbol{\theta}) &= \nabla_{\mathbf{x}} \log \hat{p}(\mathbf{x}|\boldsymbol{\theta}) - \nabla_{\mathbf{x}} \log Z_{\boldsymbol{\theta}} = \nabla_{\mathbf{x}} \log \hat{p}(\mathbf{x}|\boldsymbol{\theta}) \end{split}$$

Let define stochastic process  $\mathbf{x}(t)$  with initial condition  $b\mathbf{x}(0) \sim p_0(\mathbf{x})$ :

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}$$

 $\mathbf{w}(t)$  is the standard Wiener process (Brownian motion)

$$\mathbf{w}(t) - \mathbf{w}(s) \sim \mathcal{N}(0, t - s), \quad d\mathbf{w} = \epsilon \cdot \sqrt{dt}, \text{ where } \epsilon \sim \mathcal{N}(0, 1).$$

- **f**( $\mathbf{x}$ , t) is the **drift** function of  $\mathbf{x}$ (t).
- ightharpoonup g(t) is the **diffusion** coefficient of  $\mathbf{x}(t)$ .
- ▶ If g(t) = 0 we get standard ODE.

$$d\mathbf{x} = \mathbf{f}(\mathbf{x}, t)dt + g(t)d\mathbf{w}$$

How to get distribution  $p(\mathbf{x}|t)$  for  $\mathbf{x}(t)$ ?

Theorem (Kolmogorov-Fokker-Planck)

Evolution of the distribution  $p(\mathbf{x}|t)$  is given by the following ODE:

$$\frac{\partial p(\mathbf{x}|t)}{\partial t} = -\frac{\partial}{\partial \mathbf{x}} (\mathbf{f}(\mathbf{x},t)p(\mathbf{x})) + \frac{1}{2}g^2(t) \frac{\partial^2 p(\mathbf{x}|t)}{\partial \mathbf{x}^2}$$

#### Langevin SDE

Let consider special case of SDE with g(t) = 1 and  $\mathbf{f}(\mathbf{x}, t) = \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}|t)$ .

$$d\mathbf{x} = \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}|t) dt + d\mathbf{w}$$

Let apply KFP theorem.

$$\frac{\partial p(\mathbf{x}|t)}{\partial t} = -\frac{\partial}{\partial \mathbf{x}} \left( p(\mathbf{x}|t) \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}|t) \right) + \frac{1}{2} \frac{\partial^2 p(\mathbf{x}|t)}{\partial \mathbf{x}^2} = 
= -\frac{\partial}{\partial \mathbf{x}} \left( \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} p(\mathbf{x}|t) \right) + \frac{1}{2} \frac{\partial^2 p(\mathbf{x}|t)}{\partial \mathbf{x}^2} = 0$$

The density is  $p(\mathbf{x}|t) = \text{const.}$ 

## Langevin dynamic

Let discretize the Langevin SDE

$$\mathbf{x}_{t+1} = \mathbf{x}_t + \eta \frac{1}{2} \frac{\partial}{\partial \mathbf{x}} \log p(\mathbf{x}|t) + \sqrt{\eta} \cdot \epsilon, \quad \epsilon \sim \mathcal{N}(0, 1).$$

#### Statement

Let  $\mathbf{x}_0$  be a random vector. Then under mild regularity conditions for small enough  $\eta$  samples from the following dynamics

$$\mathbf{x}_{t+1} = \mathbf{x}_t + \eta \frac{1}{2} \nabla_{\mathbf{x}_t} \log p(\mathbf{x}_t | \boldsymbol{\theta}) + \sqrt{\eta} \cdot \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(0, 1).$$

will comes from  $p(\mathbf{x}|\theta)$ .

We could sample from the model if we have  $\nabla_{\mathbf{x}} \log p(\mathbf{x}|\boldsymbol{\theta})$ .

## Fisher divergence

$$D_{F}(\pi, p) = \mathbb{E}_{\pi} \left\| \nabla_{\mathbf{x}} \log p(\mathbf{x}|\boldsymbol{\theta}) - \nabla_{\mathbf{x}} \log \pi(\mathbf{x}) \right\|_{2}^{2} \to \min_{\boldsymbol{\theta}}$$

#### Score function

$$s(x, \theta) = \nabla_x \log p(x|\theta)$$

**Problem:** we do not know  $\nabla_{\mathbf{x}} \log \pi(\mathbf{x})$ .

#### Theorem

$$\begin{split} \boldsymbol{\theta}^* &= \operatorname*{arg\,min}_{\boldsymbol{\theta}} \mathbb{E}_{\boldsymbol{\pi}} \big\| \mathbf{s}(\mathbf{x}, \boldsymbol{\theta}) - \nabla_{\mathbf{x}} \log \boldsymbol{\pi}(\mathbf{x}) \big\|_2^2 \\ &= \operatorname*{arg\,min}_{\boldsymbol{\theta}} \mathbb{E}_{\boldsymbol{\pi}} \Big[ \| \mathbf{s}(\mathbf{x}, \boldsymbol{\theta}) \|^2 + \operatorname{trace} \big( \nabla_{\mathbf{x}} \mathbf{s}(\mathbf{x}, \boldsymbol{\theta}) \big) \Big] \end{split}$$

Here  $\nabla_{\mathbf{x}}\mathbf{s}(\mathbf{x}, \boldsymbol{\theta}) = \nabla_{\mathbf{x}}^2 \log p(\mathbf{x}|\boldsymbol{\theta})$ .

Proof (only for 1D)

# Summary

Adjoint method generalizes backpropagation procedure and allows to train Neural ODE solving ODE for adjoint function back in time.

► Fokker-Planck theorem allows to construct continuous-in-time normalizing flow with less functional restrictions.

FFJORD model makes such kind of flows scalable.
